TITLE: The Stepped-Up Development of the Chemical Industry is the Paramount Factor in the Technical Progress of the National Economy (Uskorennoye razvitiye khimicheskoy promyshlennosti - vazhneyshiy faktor tekhnicheskogo progressa narodnogo khozyaystva)

PERIODICAL: Standartizatsiya, 1958, ²² Nr 3, pp 3-6 (USSR)

ABSTRACT: Information is given on the increased production plans for 1959 through 1965 in the Soviet mechanical industry. The output of artificial fibers has to be increased by 4.6, of plastics and synthetic resins by 8, of synthetic rubber by 3.4 times over 1957 figures. In connection with the expansion of the chemical industry, it is planned to reach the following production figures by 1965: 500 million meters of woolen fabrics, 1 billion meters of silk fabrics, 480 million meters of cotton fabrics mixed with synthetic fibers, 940 million pieces of artificial astrakhan fur (5 million square meters), 515 million pairs of shoes. The plans call for the construction of 120 new and the reconstruction of 137 existing chemical plants plus new scientific and research institutions. The estimated costs

Card 1/2

28-58-3-1/32

The Stepped-Up Development of the Chemical Industry is the Paramount Factor in the Technical Progress of the National Economy

are 100 billion rubles. It is stressed that along with the expansion, the chemical industry must drastically improve production quality. The following products are mentioned as needing improvement: kapron fiber (stockings), viscose fiber (rubber industry, automobile tires), paints and dyes. Dyes of high quality are produced in too small quantity and assortment. The state standards for pneumatic automobile tires will be revised in 1958. The use of edible raw materials in the production of synthetic rubber will be stopped, and the new plants will be designed for the use of butane-butylene fractions as initial raw material. It is pointed out that nitrogenous fertilizers produced in the form of ammonium nitrate and ammonium sulphate, which in the end oxidize the soil with their residues, must be increasingly replaced by neutral and concentrated fertilizers. Production of the most effective insecticides including hexachlorane, "2,4 DU", "merkuran" etc. will be greatly increased.

TITLE: A double shaft gas turbine installation. Class 46, No. 171697

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 11, 1965, 117

TOPIC TAGS: gas turbine engine

ABSTRACT: This Author's Certificate introduces: 1. A double shaft gas turbine installation. On one shaft are a medium pressure compressor and a low pressure turbine, while on the other shaft are low and high pressure compressors and a high pressure turbine. The installation is designed for high economy under partial loads. The device has a valved bypass line which connects the air channel after the medium pressure compressor with the gas channel after the high pressure turbine. 2. A modification of this design with a regenerator heated by the gases which are partially removed after the low pressure turbines.

TITLE: Method for starting a two-shaft gas turbine engine. Class 46, No. 174041

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 16, 1965, 117

TOPIC TAGS: gas turbine engine, engine start up, gas turbine operation, ENGINE STARTER SYSTEM, ENGINE COMPRESSOR SYSTEM

ABSTRACT: This Author Certificate presents a method for starting up a two-shaft gas turbine which has the medium pressure compressor and the low pressure turbine on one shaft and the low pressure compressor and high pressure turbine on the other shaft. To permit starting with only one electric motor located on the low pressure turbine shaft, part of the air from the medium pressure compressor is ducted to the low pressure combustion chamber (see Fig. 1).

TITLE: Investigating nonsteady operation of cooled disk-type rotor of a gas turbine

SOURCE: Energomashinostroyeniye, no. 5, 1964, 6-9

TOPIC TAGS: turbine, gas turbine, gas turbine quick starting, gas turbine nonsteady operation, gas turbine disk rotor

ABSTRACT: Peak-load or reserve gas turbines in power-supply systems operate under repeated start-stop and quick-start conditions. Hence, it is essential to know the behavior of the most important gas-path parts subjected to varying high temperatures. Results of an experimental investigation of the temperature field in a disk-type rotor under nonsteady-operating conditions are reported. The temperature fields were measured under these conditions: (a) starting from the cold state without warming up; the maximum gas temperature was attained in

Card 1/2

ACCESSION NR: AP4038898

1-1.5 min, and the rated load was taken in 3.5-4 min; (b) starting with a 5-min, 40%-rpm, 520-550C-gas warm-up; and (c) starting one hour after the turbine shutdown, with the disk temperature 250-300C. Stresses in the disk (hub, tip) were estimated. These conclusions were reached: (1) Cold starting is not limited by the disk stresses; (2) The radial-blown system of cooling the test turbine is satisfactory; (3) N. A. Minaylenko's method ("Determining temperature fields and stresses in gas-turbine disks," AN UkrSSR, 1960) ensures good agreement with the experiment. TITLE: Effect of aluminum on the structure and properties of alloys of the Magnico type

SOURCE: IVUZ. Chernaya metallurgiya, no. 1, 1967, 138-141

TOPIC TAGS: magnetic alloy, aluminum containing alloy, magnetic property

ABSTRACT: The authors study the effect of aluminum on the structure and properties of anisotropic Magnico alloys. The alloys studied were smelted with an aluminum concentration of 6.2-9.5% in the charge corresponding in other components to the composition of Anko-4 alloy (GOST 4402-48). Metallographic and magnetometric methods were used in the analysis. The coercive force was taken as the criterion for determining structural changes. A U-541 installation was used for measuring the residual induction, coercive force and demagnetization curves by the ballistic method. The Curie points of the alloys were determined from the effect of temperature on their magnetic permeability. Definite structural states of the alloys were fixed by isothermal quenching from various temperatures. The process of $\beta_2 \rightarrow \alpha + \beta_2$ decay takes place in the 870-1280°C range with an incubation period which decreases with a reduction in aluminum concentration.

Card 1/2

UDC: 669.018.5:620.183

ACC NR: APT005396

The temperature corresponding to minimum incubation for $\beta_2 \rightarrow \alpha + \beta_2$ decay rises with a reduction in aluminum concentration in the alloy. There is also an expansion in the temperature region for development of this decay process as aluminum concentration decreases. Thus the temperature to which Magnico alloys are heated before quenching should be selected with regard to aluminum concentration. Aluminum concentration should also be taken into account in calculating the critical cooling rate in the upper temperature interval (1300-850°C) during heat treatment. The time necessary for reaching the maximum degree of decay decreases extremely rapidly with a reduction in aluminum concentration. For instance, an alloy with 9.5% Al requires 10-12 hours for completion of the decay process while the corresponding figure for an alloy with 7.5% Al is 10-12 minutes. The overall level of coercive force increases with a reduction of aluminum in the alloys. The results of these studies show that aluminum has a strong effect on high-temperature conversion in Magnico alloys which is detrimental to their magnetic properties. The effect of aluminum concentration on the properties of the alloys is revealed most clearly in the shape of hysteresis curves and the magnitude of maximum magnetic energy. Specimens subjected to magnetic heat treatment with subsequent annealing under optimum conditions show maximum magnetic energy with 8.5% aluminum concentration. An increase or reduction in this concentration is detrimental to the magnetic properties of the alloy. Orig. art. has: 5 figures.

TITLE: Deterioration of the magnetic properties of Magniko
alloys in the case of "lustreless" fractures

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
no.6, 1962, 14-17

TEXT: The state of Magniko alloys with lustreless fractures and
methods of re-establishing high magnetic properties in such alloys
were studied on material of the following composition:
Anko-3 (Anko-3): 19% Ni; 10.6% Al, 18.36% Co, 3.1% Cu, 0.03% C;
0.3% Si; Anko-4 (Anko-4): 13.8% Ni; 8.4% Al; 24.33% Co,
5.25% Cu; 0.03% C, 0.08% Si; produced in a 50 kg high-frequency
furnace. Conclusions: Slow cooling or isothermal holding at
900 to 1200°C produces decomposition of the solid solution into a
two-phase structure, causing a sharp drop in the magnetic
properties; the minimum coercive force is caused by changes
brought about in the alloy in the range 1100 to 1050°C and the
magnetic energy of a specimen cooled at 1075°C is only

Card 1/2

Deterioration of the magnetic ...

S/129/62/000/006/003/008
E073/E435

1.2×10^6 Gauss Oe. Such decomposition can also result from cooling the alloy in the range 1200 to 900°C at a rate below 40 to 50°C/min. In this state the material is more malleable and easier to machine. The normal high magnetic properties can be re-established by heat treatment. The following process of manufacture of Magniko type magnets proved best: smelting, isothermal annealing at 1000 to 1100°C, machining at higher rate than usual, servomagnetic treatment at 1500°C followed by the usual tempering. There are 3 figures and 1 table.

TITLE: High temperature segregation in Alnico (Magnico)
type alloys

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,
Chernaya metallurgiya, no.11, 1961, 170-175

TEXT: Preliminary tests showed that slow cooling of Alnico
alloys (Fe-Ni-Al-Co) of high coercive force through the
1300-900 °C temperature range causes a noticeable deterioration
in the magnetic properties. In order to explain this phenomenon,
determinations were made of the magnetic induction (H_c) and
coercive force (B_r) of specimens of Anco-3, Anco-4, non-standard
Alnico alloy (27% Co), and a cobalt-free Al-2 (AN-2) alloy
(26.90% Ni, 12.10 Al, 3.76 Cu, 0.01 C, 0.07 Si, 0.011 S, remainder
Fe). 50 kg batches of the test alloys were melted in a high-
frequency furnace and 27 x 7 x 7 mm test specimens prepared from
50 x 30 x 30 mm castings previously subjected to heat treatment
(up to 1300 °C) and ground on all sides. Micrographic examination

was made of specimens etched with 5% alcoholic solution of HNO₃ and 15% aqueous solution of HNO₃. The segregated phase was separated by anodic dissolution using an electrolyte consisting of 5% HCl and a complexing agent (nature not stated) at a low current density (50 mA/cm²). This electrolyte was found to be the most selective with regard to the various phases present in the specimens. The deposit of the unknown phases thus obtained was then subjected to X-ray structural analysis using CoK_α and FeK_α radiations. Before testing, the specimens were homogenised at 1300 °C, held isothermally at various temperatures in the range 1250-800 °C, and air-quenched. It was found that a structural breakdown occurs in Alnico alloys in the temperature interval of 1200-900 °C and results in the segregation of a face-centred cubic phase with crystal lattice parameter $a = 10.2\text{\AA}$ from the starting solid solution. The segregation goes on even at temperatures below 900 °C, but the rate of the segregation then drops to such an extent that the process is masked by the $\beta_2 \rightarrow \beta + \beta_2$ transformation. The new phase formed during the segregation is enriched in Co and Fe, its hardness is lower than Card 2/4

that of the matrix and it is deposited mainly in sections of axes of dendrites, grain boundaries and substructure. The high-temperature segregation is shown clearly only in cobalt-containing alloys and the presence of the new phase can be detected visually by a change of fractured surfaces from the usually bright appearance to a dull one. Under plant conditions, the dull appearance of the fractured surface is caused by slow cooling or by a high-temperature thermal treatment of the magnets (1200-900 °C). In the case of Anco-3 alloys, the formation of this new phase can be prevented by ensuring that the cooling rate does not drop below 50 °C/min. Although the segregation of the new phase leads invariably to a deterioration in magnetic properties, the original magnetic properties are restored by repeating the homogenisation treatment.

and Alnico alloys

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 3, 1962, 311 - 312

TEXT: The magnetic properties of Alni and Alnico alloys, which are used
for permanent magnets, depend on their macro- and microscopic structures.
A chemical method of revealing these structures has been developed and a
method of determining grain orientation is described. The alloys A₄2
(An2), A₄Ko 3 (Anko 3) and A₄Ko4 (Anko 4) were used as specimens and the
following compositions as etching agents:No. 1: 100 ml HCl + 10 ml HNO₃ + 25 g K₂Cr₂O₇ + 100 ml H₂ONo. 2: 75 ml HCl + 25 ml HNO₃No. 3: 15 ml HNO₃ + 85 ml H₂ONo. 4: 5 ml HNO₃ + 95 ml ethyl alcohol

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 6, 1966,
33-36
TOPIC TAGS: high alloy steel, carbon , thermal decomposition, magnetic
property, magnetic alloy
ABSTRACT: Studies were made of alloys containing 0.20 to 0.2% carbon,
with a basic chemical composition corresponding to alloy ANKO-4
(GOST 4402-48). The investigation was carried out by a comparison of
microstructural and magnetometric analyses. To determine the structural
states of the alloy, the method of isothermal quenching from different
temperatures was used. A study was made of the effect of carbon on high
temperature $\beta_2 \rightarrow \alpha + \beta_2$ -decomposition (the temperature region above
850°C) and of low temperature dispersive $\beta_2 \rightarrow \beta + \beta_2$ -decomposition
(below 850°C), leading to a high state of coercivity. Experimental
results are shown in graphic form. Overall conclusions are as follows.

Carbon in Magnico alloys promotes the development of the $\beta_2 \rightarrow \alpha + \beta_2$ decomposition, which has a negative effect on the magnetic properties of the alloy. The Magnico alloys can be characterized by their temperability, that is, by the diameter of a cylindrical magnet which, after hardening, is characterized by the absence of the $\beta_2 \rightarrow \alpha + \beta_2$ decomposition. The temperability of Magnico alloys increases with a decrease in the carbon content. In magnets of small cross section, good magnetic properties can be obtained with a carbon content up to 0.05%. TITLE: Characteristics of high-temperature decomposition in magnico alloys

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 2, 1965, 7-10

TOPIC TAGS: magnico alloy, permanent magnet, alloy phase decomposition, high temperature decomposition, coercive force

ABSTRACT: Since it had been found that magnico alloys with the same composition and with similar $\beta_2 \rightarrow \beta + \beta_2$ decomposition had a different tendency toward high-temperature $\beta_2 \rightarrow \alpha + \beta_2$ decomposition, and therefore substantially different magnetic properties, the authors investigated the characteristics of high-temperature decomposition of this alloy, using Anco-4 cast alloy and its various nonstandard modifications. Cast and prehomogenized specimens were isothermically treated or cooled at a controlled rate from 1300-800°C. The magnetic properties of the specimens were measured and the microstructure studied. The coercive force was used as the main structure-sensitive characteristic. It was demonstrated that the rate of decomposition depended on the rate of cooling the specimens from 1300-800°C and, for isothermal conditions, on the holding time at a given temperature. In alloys with an initial cast structure, decomposition occurred along the axes of the

L 34064-65

ACCESSION NR: AP5005096

dendrites and grain boundaries, whereas in the prehomogenized specimens it took place only along the grain boundaries. Acicular particles of the separating β_1 -phase develop in slip planes (110) of the β_2 -phase (matrix) and often alternate periodically, forming a regular network. Decomposition was extremely easy to produce near internal cracks. In alloys plastically deformed at elevated temperatures, a grain texture was formed identical to that of the β_1 -phase separations. The particles of the β_1 -phase were preferentially arranged in the same slip planes (110) along which shear occurred. Thus it was found that high-temperature decomposition in magnico alloys, which lowers their magnetic properties, is due to imperfection of their crystal structure and the inevitable presence of carbon in them. The change in the carbon content (0.02-0.05%) under industrial conditions is probably one of the chief causes for variations in the behavior of magnico alloys. This adverse effect of carbon can be suppressed by alloying the magnico alloys with carbide-forming elements. Orig. art. has: 1 table and 5 figures.

TOPIC TAGS: alloy, magnesium alloy, aluminum alloy, cobalt alloy, copper alloy, magnetic metal, magnetic field, thermomagnetic effect

TRANSLATION: A study of alloys of the Fe-Ni-Al-Co-Cu system has shown that magnetic texture (MT) is created in a series of alloys by magnetic field superposition in a narrow interval of 800-700°C, corresponding with the start of a 2-phase $\beta_2 \rightarrow \beta + \beta_2$ - disintegration. During this process there occurs a temperature hysteresis in the formation and disappearance of MT, which reflects the hysteresis of the phase transformation. It is shown that the state of single-phase θ alloys does not necessarily determine the possibility of MT formation. The alloys are susceptible to thermomagnetic processes only when the secreting β -phase immediately becomes ferromagnetic. During the thermomagnetic processing with a continuous cooling in the magnetic field,

0

MT is formed in the initial moment of disintegration. A further isometric soaking or a slow cooling without a field help to form MT and to increase H_c without altering B_r . It is shown that MT remains stable during the second annealing and will disintegrate completely only at temperatures over 850°C. 4 figures, 1 table, and 4 references.

PERIODICAL: "Khimiya i Tekhnologiya Topliva i Masel" (Chemistry and Technology of Fuels and Lubricants) 1957, No. 4, pp. 59-61 (USSR).

ABSTRACT: Improvements achieved in cleaning the effluent water from petroleum products are described. The main contribution to this improvement was the construction of a large settling lagoon (surface area 14 000 m², depth 1.5 to 2 m) in which the effluent water was kept for 2 days. The mean content of petroleum products in the effluent decreased from 350 mg/l (1953) to 28-46 mg/l in 1956. There are 2 tables.

TITLE: "Industrial Analyses of Natural Fluorites (Technické analýza přírodných fluoritů)

PERIODICAL: Českáček Listy, 1958, Vol 52(82), Nr 10, pp 2008-2009
(Czechoslovakia)

ABSTRACT: In industrial practice the fluorine content of fluorite is usually determined indirectly by the determination of total calcium and the calcium carbonate. Fluorite is decomposed by concentrated sulphuric acid after roasting. Silicic acid with several exposures to hydrofluoric acid. Apart from calcium fluoride, silica and barium oxide (barite) are determined. This method is quite lengthy and tedious, as well as involving a number of errors. The present method is based on the well known reaction which involves the decomposition of fluorite by a mixture of boric and perchloric acids; the fluorine is volatilised very quickly in the form of a complex fluoroborate, the ions released form easily soluble chlorates and chlorides so facilitating the process.

Card 1/5 Standard samples were prepared from natural materials.

Calcium fluoride was separated from optical fluorite (Bottlerberg West Germany). A gravimetric check was carried out and it was found to be 99.7% standard silicon dioxide was prepared from silica by allowing it to stand for several hours in hydrochloric acid. Its purity was found to be 98.04% by the standard method. A borate standard of 99.22% purity was prepared in a similar fashion. An 0.1 M volumetric solution of "Cooperoxen III" was prepared by dissolving diiodum ethylene diuine terbraceate (Stauffer Co., Norfin) (37.2 g) in distilled water (1 l). It was standardised against a solution of a calcium salt. All other chemicals were of maximum purity.

Decomposition of fluorite. Various quantities of standard fluorite were decomposed with 5 ml of dilute perchloric acid (1:3) saturated at 50°C with boric acid, within <10 mins. The mixture was evaporated to dryness, the residue dissolved in hot water and examined for the presence of fluoride colorimetrically. The decomposition is complete even with large amounts of fluoride (1.6) and the glass breakers are not affected. Examination of standard mixtures of silicon dioxide, calcium fluoride and barium sulphate by this process shows that the decomposition of fluorite in the presence of silicon dioxide and other fractions occurs reliably and does not lead to significant losses of the fractions so that it is possible to use this method in industrial practice, application. A finely powdered sample (1.6) of standard fluorite was added into a beaker, dilute perchloric acid (1:3) saturated with boric acid at 50°C (1.5 ml) poured in covered with a watch-glass, rinsed and then evaporated to dryness. After cooling concentrated hydrochloric acid (5 ml) and hot water (50 ml) were added and the mixture allowed to stand 10 mins. The silicic acid liberated is filtered off, washed, and the amount determined by difference after repeat dilution with hydrofluoric acid. The residue in the crucible is stirred with several millilitres of dilute hydrochloric acid (1:4), diluted with hot water,

Card 2/5

Card 4/5

on a small filter and weighed. If the
crucible and the basic sulphate weighed.
content is high then it is necessary to purify by fusion
and reprecipitation. The combined filtrate are made
up to the mark in 250ml standard flask mixed and
pipetted off in convenient portions for the determination
of calcium. If the sample has a low content of elements
of the ammonia group the pipetted portion is moderately
diluted, a 20% solution of triethanolamine (5 ml) added,
made strongly alkaline with sodium hydroxide and
titrated with a standard solution of complexone to
moxide. Where there are high concentrations of iron
and aluminium, these elements are removed by hydrolytic
precipitation with uretrophine, centrifugally
and then the determination carried out as above. The
correction for calcium carbonate was carried out
indirectly by a volumetric determination of carbon
dioxide content. Where there are high cuprate contents,
it is necessary to carry out the classical determination
after the decomposition of the sample with dilute
acetic acid. These methods were used for the analysis
of a series of samples from different localities. The
method, according to the authors' results, gives
comparable values to those obtained by the classical
method. The proposed method was used, with complete
satisfaction, in the control of the flotation process
and the time needed was about one third of that of the
classical method.

ABSTRACT	: The synthesis of urea which is used to form a poly(1,3-phenylidicarboxylic acid) is utilized in the synthesis of poly(1,3-phenylidicarboxylic acid). The polymer is subjected to thermal treatment in a heating furnace (600-700°), the formation of very stable hydroxy-ureidized carbon are not removed until 600-700°. Infrared spectrum of the polymer during synthesis results in losses of CO ₂ carbon dioxide and water. In the case of urea, the content of CO ₂ , the amount of water to about 20%. To correlate their errors in the calculation of the data, the following information is given: the value of 1601 and a titration of carboxylic acid.

ABSTRACT : are increased accordingly. Hg is determined in the distillate by extractive titration with a solution of dithizone in CCl_4 or (in the case of a high content of Hg) gravimetrically by the mercaptophenyl-thiathiodiazolone method. The described method is suitable for accurate control of the progress of roasting of lean Hg-ores.

H_2SiO_3 which separated during this process is filtered off after 10 minutes and determined by the usual method of weight loss after several evaporation with HF. The residue is treated with several ml of HCl (1 : 4), diluted with hot water, filtered off, calcined, and weighed as $BaSO_4$. The combined filtrates are diluted with water to 250 ml and, using an aliquot of the resulting solution, Ca is determined by titration with 0.1 M Complexone III solution in strongly alkaline medium using murexide as the indicator. Small amounts of metals of the NH_4OH group are masked by adding 5 ml 30% triethanolamine solution; at greater Fe and Al contents these metals are previously separated by precipitating with urotropine. In order to

correct for CaCO_3 , the CO_2 content is found by
an indirect titrimetric determination; however,
large quantities of CaCO_3 have to be removed
by the usual method after a preliminary de-
composition with a dilute CH_3COOH solution. --

Use of the tungstate method for determining calcium in
the technical analysis of carbonate rocks. Pavel Pavonina
Vzduch Moli. Grot. Dikaren. Cirkulare Rep. 25, 279-80. In
English, 292(1950). Instead of pptg. the Ca as oxalate and
the Mg as $Mg(NH_4)_2PO_4 \cdot 6H_2O$, it is recommended to make a
double pptn. with oxine and det. the Mg by bromometric
titration of the ppt. Then evap. the filtrate to dryness, ex-
pel NH₄ salts and destroy org. matter by heating in a Pt
dish. Ppt. the Ca at pH 8-8.5 by adding 15% Na₂WO₄ soln.
at 80°. The filtered, washed, and ignited ppt. contains
19.47% Ca.

Alteration of the non-protein-nitrogen of blood by the action of subcutaneous administration of picrocaccine. S. A. ROVINSKAYA (Russ. J. Physiol., 1926, 13, 627-635).—Subcutaneous administration of picrocaccine in therapeutic doses does not affect the blood-uric acid, but brings about a decrease in the amino-nitrogen and an increase in the residual nitrogen, the latter being more marked on a basis and less marked on an acid diet. When the amino-nitrogen rises the residual nitrogen tends to fall and vice versa.

Blood-lipase in children under the influence of pilocarpine with an acid or alkaline diet. S. A. PUGACHEVSKA (Ross. J. Physiol., 1930, 13, 745-749).—The blood-lipase content does not change under the action of pilocarpine, but differs much from individual to individual, and the same child exhibits marked variations. Variations of catalase curve of blood after introduction of pilocarpine on an acid or alkaline diet. S. A. Povarzinskaya (Russ. J. Physiol., 1930, 13, 186-198).—The curves representing the catalase content of blood at various times after subcutaneous injection of pilocarpine are of a uniform type for children receiving an alkaline but not an acidic diet; where a mixed diet is taken, the curves are of a mixed type. The catalase-time curves for children on an alkaline diet not receiving pilocarpine are not of a uniform type. The catalase curves vary irregularly for the same individual according to the day and hour at which the blood is taken. No parallelism is found between blood-catalase and haemoglobin contents.
